

Fall 2016.

Wedding Planner Application

OOP244 Assignment V1.0

When planning a wedding, the most important thing is to provide all required items on time in order to ensure that the entire ceremony progresses smoothly.

Your job for this project is to prepare an application that manages the list of goods required for a wedding and the delivery date of those goods, if applicable. Your application keeps track of the quantity of goods needed and the quantity on hand, and stores this information in a file for future use.

The types of goods needed for a wedding are divided into two categories;

- OnShelf: Items that can be purchased from a store and are available when requested.
- Custom: Items that are made to order and will only be ready at some future date.

To prepare the application you need to create several classes that encapsulate the different tasks at hand.

CLASSES TO BE DEVELOPED

The classes required by your application are:

Date	A class that manages a date.
ReadWrite	<p>A class that enforces <code>iostream</code> read and write functionality for derived classes. An instance of any class derived from <code>ReadWrite</code> can read from or write to the console, or be saved to or retrieved from a text file.</p> <p>Using this class the list of goods can be saved to a file and retrieved later, and individual good specifications can be displayed on screen or read from keyboard.</p>
Good	A class derived from <code>ReadWrite</code> , containing general information about an item needed for the wedding, like the name, Universal Product Code (UPC), price, etc.
OnShelf	A class holding information for OnShelf items derived from the <code>Good</code> class that implements the requirements of the <code>ReadWrite</code> class (i.e. implements the pure virtual methods of the <code>ReadWrite</code> class)
CustomMade	A class derived from the <code>Good</code> class that implements the requirements of the <code>ReadWrite</code> class and holds a delivery date.
WPlanner	The class that manages <code>OnShelf</code> and <code>CustomMade</code> goods. This class manages the listing, adding and updating the goods for the wedding.

PROJECT DEVELOPMENT PROCESS

Your development work on this project has five milestones and therefore is divided into five deliverables. Shortly before the due date of each deliverable a tester program will be provided to you. Use this tester program to test your solution and use the script to submit each of the deliverables. The approximate schedule for deliverables is as follows

- Date class Due: Nov 3rd
- ReadWrite class Due: Nov 6th
- Good class Due: Nov 15th
- OnShelf and CustomMade classes Due: Nov 20th
- WPlanner class. Due: Nov 28th

FILE STRUCTURE FOR THE PROJECT

Each class will have its own module; a header (.h) file and an implementation (.cpp) file. The names of these files should be the same as the class name.

In addition to the header files for each class, create a header file called `wpgeneral.h` that defines general values for the project, such as:

<code>TAX (0.13)</code>	The tax rate for the goods
<code>MAX_UPC_LEN (7)</code>	The maximum size of a UPC code
<code>MIN_YEAR (2000)</code>	The min year used to validate year input
<code>MAX_YEAR (2030)</code>	The max year used to validate year input
<code>MAX_NO_RECS (2000)</code>	The maximum number of records in the data file.

Include this header file wherever you use these values.

Enclose all the code developed for this application within the `ict` namespace.

MILESTONE 1: THE DATE CLASS

The `Date` class encapsulates a single date value in the form of three integers: year, month and day. The date value is readable by an `istream` and printable by an `ostream` using the following format: `YYYY/MM/DD`

Complete the implementation of the `Date` class under the following specifications:

Member Data (attributes):

<code>int year_;</code>	Year; a four digit integer between <code>MIN_YEAR</code> and <code>MAX_YEAR</code> , as defined in <code>wpgeneral.h</code>
<code>int mon_;</code>	Month of the year, between 1 and 12
<code>int day_;</code>	Day of the month; note that in a leap year February has 29 days, (see <code>mday()</code> member function)

`int readErrorCode_;` Error code which identifies the validity of the date and, if erroneous, it identifies the part that is incorrect. Define the possible error values in the `Date` header-file as follows:

```
NO_ERROR    0  -- No error - the date is valid
CIN_FAILED  1  -- istream failed on accepting information
YEAR_ERROR  2  -- Year value is invalid
MON_ERROR   3  -- Month value is invalid
DAY_ERROR   4  -- Day value is invalid
```

Private Member functions (private methods):

`int value() const;` *(this function is already implemented and provided)*

This function returns a unique integer number based on the date. You can use this value to compare two dates. If the `value()` of one date is larger than the value of another date, then the former date (the first one) follows the second.

`void errCode(int errorCode);`

Sets the `readErrorCode_` member variable to one of the possible values listed above.

Constructor:

This constructor accepts three arguments to set the values of `year_`, `mon_` and `day_`. It also sets the `readErrorCode_` to `NO_ERROR`.

Public member-functions (methods) and operators:

Relational operator overloads:

```
bool operator==(const Date& D)const;
bool operator!=(const Date& D)const;
bool operator<(const Date& D)const;
bool operator>(const Date& D)const;
bool operator<=(const Date& D)const;
bool operator>=(const Date& D)const;
```

These operators return the result of comparing the left operand to the right operand. These operators use the `value()` member function in their comparison. For example `operator<` returns true if `this->value()` is less than `D.value()`; otherwise returns false.

`int mdays() const;` *(this function is already implemented and provided)*

This function returns the number of days in the month based on `year_` and `mon_` values.

Accessor or getter member functions (methods):

`int errCode() const;` Returns the `readErrorCode_` value.

`bool bad() const;` Returns true if `readErrorCode_` is not equal to zero.

IO member-functions (methods):

```
std::istream& read(std::istream& istr);
```

Reads the date in following format: YYYY/MM/DD (e.g., 2015/03/24) from the console. This function does not prompt the user. If the `istream` (i.e., `istr`) object fails at any point, this function sets `readErrorCode_` to `CIN_FAILED` and does **NOT** clear the `istream` object. If the `istream` object reads the numbers successfully, this function validates them. It checks that they are in range, in the order of year, month and day (see the `wpgeneral` header-file and the `mday()` function for acceptable ranges for years and days respectively). If any number is not within range, this function sets `readErrorCode_` to the appropriate error code and omits any further validation. Irrespective of the result of the process, this function returns a reference to the `istream` (i.e., `istr`) object. `std::ostream& write(std::ostream& ostr) const;`

This function writes the date to the `ostream` (i.e., `ostr`) object in the following format: YYYY/MM/DD, then returns a reference to the `ostream` object.

Non-member IO operator overloads: (Helpers)

After implementing the `Date` class, overload the `operator<<` and `operator>>` to work with `cout` to print a `Date`, and `cin` to read a `Date`, respectively, from the console.

Use the `read` and `write` member functions. **DO NOT** use friends for these operator overloads.

Include the prototypes for these helper functions in the `date` header file.

Preliminary task

To kick-start the first milestone clone or download the Visual Studio project, or individual files for milestone 1 from https://github.com/Seneca-244200/OOP_MS1.

Start your development and test your implementation with tester number 1 and work your way up to tester number 4. Then compile your code with the main tester (`oop_ms1_tester.cpp`) and make sure your code passes all the tests.

If not on matrix already, upload your `Date.cpp`, `Date.h`, `wpgeneral.h` and `oop_ms1_tester.cpp` to your matrix account. Compile and run your code and make sure everything works properly.

Then run the following script from your account: (replace `profname`.`proflastname` with your professors Seneca userid)

```
~profname.proflastname/submit ipc_ms1 <ENTER>
```

Following the instructions, test and demonstrate execution of your program.
